1. QUESTIONS

**Q1:** A (digital) signature scheme consists of three probabilistic polynomial-time algorithms (Gen, Sign, Vrfy). Explain each algorithm with its input and output.

**A1:** These 3 algorithms are:

- *Gen*: on input a security parameter  $1^n$ , outputs public key  $pk$  and secret key  $sk$ .
- *Sign*: on input a private key  $sk$  and a message  $m$ , outputs a signature  $\sigma$ .
- *Vrfy*: on input a public key  $pk$ , message  $m$  and a signature  $\sigma$ , outputs 1 or 0.

**Q2:** Compare signature schemes with MAC schemes.

**A2:** For MACs:

- Only the holder of the key can verify it.
- You can't transfer a MAC to some other party.
- Does not have non-repudiation.
- Shorter in length and faster to compute.

For Digital Signatures:

- Anyone can verify it (with the public key).
- You can transfer the signature to some other party.
- Has non-repudiation.
- Longer keys than MAC, slower to compute.

**Q3:** Formally define security (existential unforgeability against adaptive chosen message attacks) of a signature scheme.

**A3:** The  $\text{Sig-Forge}_{\mathcal{A}, \Pi}(n)$  experiment is defined in the algorithm 1 below.

**Q4:** Let  $\Pi$  be a secure signature scheme for messages of fixed length  $l$ . Construct a signature scheme based on  $\Pi$  that is secure for arbitrary-length messages. You can make use of any crypto-primitive you have learned. (No security proof is needed.)

---

**Algorithm 1** Sig-Forge<sub>A,Π</sub>( $n$ ) experiment

---

Chal generates a public and private key pair  $(pk, sk) \leftarrow Gen(1^n)$ .  
 $\mathcal{A}$  obtains  $pk$ , and is given oracle access to  $Sign(\cdot)$ . It can send a message  $m'$  and it will have in return  $\sigma' = Sign_{sk}(m')$ .  
 After some time,  $\mathcal{A}$  send  $m, \sigma$  to Chal, where  $m$  has not been used in oracle access before.  
**if**  $Vrfy_{pk}(m, \sigma) = 1$  **then**  
     output 1,  $\mathcal{A}$  wins.  
**else**  
     output 0.  
**end if**

---

**A4:** This is known as Hash-and-Sign paradigm. Let  $\Pi$  be  $(Gen, Sign, Vrfy)$ , we will construct  $\Pi'$ .

- $Gen'$ : Same as  $Gen$ .
- $Sign$ : on input a private key  $sk$  and a message  $m$ , outputs a  $Sign_{sk}(H(m))$ .
- $Vrfy$ : on input a public key  $pk$ , message  $m$  and a signature  $\sigma$ , outputs  $Vrfy_{pk}(H(m), \sigma)$ .

Here  $H$  is a collision resistant hash function.

**Q5:** Assume Charlie, acting as a certificate authority (CA), issues a certificate for Bob. Charlie's signature public key is  $pk_C$  and he always issues certificates only to the trustworthy people. Assume further that Bob's key  $pk_B$  is a public key for a signature scheme. Charlie's certificate for Bob looks like  $cert_{C \rightarrow B} = Sign_{sk_C}(\text{Bob's key is } pk_B)$ . Bob issues a certificate for Alice of the form  $cert_{B \rightarrow A} = Sign_{sk_B}(\text{Alice's key is } pk_A)$ . Now, Alice wants to communicate with some fourth party Dave who knows Charlie's public key  $pk_C$  (but not Bob's). Assume Charlie is offline now. Suggest a solution by which Alice can convince Dave that  $pk_A$  is her authentic key, without any party having access to Charlie (since Charlie is offline).

**A5:** Alice sends  $\langle \text{Alice}, pk_A, cert_{B \rightarrow A} \rangle$  to Dave. Dave can then ask Bob for  $cert_{C \rightarrow B}$ , which Dave can verify with  $pk_C$ . After that verification, Dave knows that  $B$  must be trustworthy because  $C$  issued a certificate to it. Furthermore, it can trust  $pk_B$  and use this  $pk_B$  to verify  $cert_{B \rightarrow A}$ , which reveals that  $pk_A$  is the correct public key of Alice.
